## ABSTRACT:

This report provides a comprehensive analysis of migration and unemployment data of Canada using K-Means clustering and time-series forecasting techniques. The code begins by preprocessing data, applying clustering algorithms, and evaluating silhouette scores to identify optimal cluster numbers. Visualizations, including scatter plots and line graphs, aid in interpreting cluster patterns and understanding trends in unemployment and migration over time. Additionally, the code employs exponential curve fitting to provide forecasts for these variables up to the year 2030. This integrated approach allows for a nuanced exploration of patterns, cluster characteristics, and future projections within the context of the given data.

## INTRODUCTION:

As individuals move in response to economic opportunities or challenges, their migration decisions contribute to both the alleviation and exacerbation of unemployment in different regions. This report acknowledges the multifaceted nature of this relationship and aims to shed light on the nuanced ways in which migration interacts with unemployment within Canada. By examining historical trends, employing advanced analytical techniques, and considering the impact of migration on local labour markets, this report seeks to offer a comprehensive understanding of how migration shapes unemployment dynamics over time. The findings presented herein aim to contribute valuable insights for policymakers and stakeholders grappling with the intricacies of economic planning and workforce management.

In the cluster graph of Canada, with three distinct clusters, each representing different combinations of net migration and unemployment rate, several notable patterns emerge.

The lower right corner of the graph is characterized by higher unemployment rates and lower net migration, suggesting a region where economic conditions might be less favourable, potentially leading to increased unemployment and reduced attractiveness for migration.

Conversely, the upper left corner signifies higher net migration and lower unemployment, pointing to areas with positive economic conditions and opportunities, likely drawing individuals due to better employment prospects.

In the middle-left portion of the graph, an intermediate cluster is observed. This cluster exhibits a balance between net migration and unemployment rate, indicating regions where economic conditions may not be as extreme as in the other clusters.

The line graph illustrates Canada's historical net migration trends, while the forecast graph extends predictions until 2030 using an exponential curve fitting model. The increasing net migration is likely influenced by factors such as economic opportunities, political stability, a renowned education system, favourable immigration policies, and high-quality living standards. These analyses provide valuable insights for policymakers, offering a concise overview of past trends and future projections, aiding in informed decision-making regarding demographic changes in Canada.

The declining trend in Canada's unemployment rate, as depicted in the line graph, signifies a sustained improvement in the employment landscape over the observed years. The forecast graph extends this positive trajectory until 2030, projecting a continued decrease in unemployment. Contributing factors to this favorable trend may include robust economic growth, successful implementation of effective employment policies, a diversified job market, and investments in education and skill development. Additionally, the nation's resilience in the face of global economic challenges and a proactive response to changing workforce dynamics could play crucial roles in the diminishing unemployment rate.

## CONCLUSION:

In conclusion, the comprehensive analysis of migration and employment trends in Canada reveals significant patterns and projections. The line graphs depict historical trends, with net migration consistently increasing over the years and the unemployment rate steadily decreasing. The forecast graphs extend these trends into the future, suggesting a continued rise in migration and a sustained decline in unemployment until 2030. Positive economic indicators, stable political conditions, and effective policy measures appear to contribute to these trends. The findings provide valuable insights for policymakers, indicating a dynamic and resilient Canadian socio-economic landscape. Continued attention to factors influencing migration and employment, coupled with proactive policy adjustments, will be essential for capitalizing on these positive trends and addressing potential challenges in the years ahead.
